## **Abnormal Vital Signs/Labs**

## **Asymptomatic Hypertension**

A hypertensive emergency is elevated BP **AND** <u>target organ damage</u> with neurological symptoms, chest pain, or acute SOB. This is **RARE** and requires an ambulance to the ED.

Severe hypertension, often with mild headache, is more common and is <u>not</u> an emergency.

- 1. Rest the patient in a quiet room for 10 mins and recheck BP this will work in many cases. If BP remains elevated, plan to reduce BP over days not hours
- 2. Check for patient adherence to medications and restart meds before adding on new medications. If adherent, consider increasing the dose of current meds
- 3. Check back frequently over the next couple of weeks, including blood work with renal function
- 4. Add in whichever medication is reasonable, given the patient's other conditions, and slowly reduce blood pressure over weeks
- 5. Contact the <u>RACE line</u> for specific recommendations, if needed

## Refer to the ED if:

HTN (any measurement) and:

- Chest pain/CHF
- Pregnant—preeclampsia
- Focal neuro findings
- Hyperacute renal failure or Anuria
